**Summary**

The aim of this study was to determine the effect of *Saccharomyces cerevisiae* (SC) on the morphological and histochemical properties of duodenum and duodenal submucosal glands of rabbits. Twenty 5-6 weeks old male New Zealand White Rabbits were obtained from the experimental animal laboratory of Uludag University, Bursa. The rabbits were divided randomly into two groups for 90 day. The first group (control group) received the basal diet, the second group (SC group) received basal diet supplemented with *Saccharomyces cerevisiae* at a level of 3 g/kg of feed. Duodenal tissue were taken at the end of the experiment from duodenum of animals and fixed in 10% neutral buffered formalin and embedded in paraffin. Sections were stained for localizing and characterizing glycoproteins (GPs) and morphometric measurements. In this study, the total mucosa, villus heights and gland depth of the duodenum were found to be longer than those of the control group in the SC group. However, duodenal crypt depth was greater in the duodenum of control groups, but no significant difference between the groups. The Goblet cells showed similar reaction in the both groups. Brunner glands were similar stained with AB pH 1, pH 2.5 and PAS/AB pH 1 in the both groups. However, they showed stronger positive reaction with PAS and PAS/AB pH 2.5 staining in the SC group compared with the control. In conclusion, the addition of SC to the diet of rabbits increased the total mucosa, villus height, and gland depth. However, the addition of SC also little affected the histochemical features of the duodenum by increased the secretion neutral and acidic mucins in the Brunner’s glands. Therefore, it may be proposed that higher doses of *Saccharomyces cerevisiae* may be used for digestive health.

INTRODUCTION

Probiotics are preparation of live microorganisms (like Lactobacillus acidophilus, Streptococcus faecium and Saccharomyces cerevisiae), which have beneficial effects on the health of the human or animal when administered adequately [1]. Several commercial formulations of Saccharomyces cerevisiae (SC) or its derivatives are used as prebiotics or probiotics in animal diets or feed additives. There have been numerous studies in humans and animals on the ability of probiotics to change the types and numbers of gut microflora [2-4]. Probiotics inhibit the growth of pathogenic microorganisms and provide digestive enzymes, a desirable effect for the host, and as a result changes in the intestinal microflora, antibiotic production, and synthesis of lactic acid leading to lowering of the intestinal pH, adhesion or colonization to intestinal mucosa and prevention of ammonium synthesis [5-6]. However, probiotic Saccharomyces spp may also help to reestablish a normal gut function after long term antibiotic therapy [7]. Saccharomyces spp have protective effects, and specific activities, against various enteric pathogens [8].

Currently there are only two probiotics approved for rabbits in the EU. One of them is bacterial, Bacillus cereus var. toyoi, the other is yeast, Saccharomyces cerevisiae strain NCYC Sc47 [9]. Studies with probiotics in rabbits are less than in other monogastric farm species. Because the rabbits have a high prolific nature, rapid growth rate, feed efficiency and economic management, they have been used as material in the present study.

However, there are no conclusive data on the effects in the duodenum when live yeast is used as a dietary supplement. Therefore, the objective of the present study was to assess the effects of a dietary supplement of Saccharomyces cerevisiae (live yeast culture) on the morphometric characteristics and histochemical activity of the duodenum in the rabbits.

MATERIAL and METHODS

Animals and Feeding

Twenty, five-six weeks old male New Zealand White rabbits with a mean body weight of 1.000 g were included in this study. The rabbits were housed individually in metal cages, feed and water were offered ad libitum to the rabbits throughout the 90-day trial. After adaptation, rabbits were equally divided in two groups. The first group of animals (basal diet group) was fed with a standard feed. Basal diet (pelleted) was formulated to contain 2.500 kcal ME/kg metabolizable energy, 16% crude protein and was designed to meet maintenance requirements according to the National Research Council (NRC). The second group (SC diet group) was fed with Saccharomyces cerevisiae live yeast culture (Yea Sacc, Altech, Nicholasville: 1x10⁶ CFU g⁻¹) added at concentration 3.0 g/kg into the basal diet (Table 1). The experimental protocols were approved by the Animal Care and Use Committee of Uludag University and are in accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals (2010 09/01).

Histology and Morphometric Analysis of the Duodenum

At the end of the experimental period the rabbits were slaughtered and duodenum samples approximately 3-4 cm below the pylorus were taken out. Samples were fixed in 10% neutral buffered formalin. The routine histological methods were applied to the samples and embedded in paraffin. Five µm thick sections were cut from paraffin blocks, mounted on slides, and dried overnight. After dewaxing and rehydration, sections were stained by the Crossman’s triple stain for morphometric examination and duodenal mucosa morphology. Moreover, histochemical techniques were used to distinguish the duodenal glycoproteins (GPs).

The villus height, the depth of the crypts, glands and

total mucosa were measured and micrographs were taken with Nikon 80i microscope. The villus height was measured from the villus tip to villus-crypt junction level for randomly 5 villi per section. Crypt depth was measured from the villus-crypt junction to the lower limit of the crypt was estimated for 5 corresponding crypts per section \[^{10,11}\]. The thickness of Brunner’s glands was measured from the lower limit of the crypt to the tunica muscularis. Total mucosa thickness was measured from top of the villus to the lower limit of the crypt. Fig. 1 illustrates the measurements that were made.

**Histochemistry**

Sections were stained with histochemical procedures for glycoproteins (GPs) identification;

1. PAS (Periodic Acid-Schiff’s reagent) to demonstrate neutral mucosubstance \[^{12}\].

2. AB pH 2.5 (Alcian Blue 8GX pH 2.5) to demonstrate acidic GCs with carboxylated and sulphated esters \[^{13}\].

3. AB pH 1.0 (Alcian Blue 8GX pH 1.0) to demonstrate GPs with O-sulfate esters \[^{13}\].

4. AB pH 2.5/PAS (Alcian Blue 8GX pH 2.5/Periodic Acid-Schiff staining) to demonstrate neutral and/or acid rich GCs \[^{14}\].

5. AB pH 1.0/PAS to demonstrate GPs with O-sulfate esters, periodate-reactive vicinal diols, and presence of GPs with O-sulfate esters together with periodate-reactive vicinal diols \[^{14}\].

All the slides were coded so that the investigator was blinded to staining for each slide and graded them according to the following scale: - no staining, + slight, ++ medium, +++ strong.

**Statistical Analysis**

Statistical analysis of results was performed by Mann Whitney U test (SPSS 16.0). Values are presented as means±SE. Group differences were declared significant at P<0.05.

**RESULTS**

Morphology results of the total mucosa, villus height, crypt depth and gland depth are presented in Table 2. In this study, the total mucosa, villus heights and gland depth of the duodenum were found to be longer than those of the control group in the SC group, but there was no statistically significant (P>0.05) difference between groups. However, duodenal crypt depth was decreased in rabbits fed with SC compared with control rabbits but not statistically significant (P>0.05).

The implementation of different histochemical techniques to demonstrate the presence of GPs in the goblet cells showed a similar pattern of distribution at both groups (Table 3). The Goblet cells showed a strong positive reaction with the PAS (Fig. 2), and PAS/AB (pH 2.5, pH 1) staining, while no reaction with the AB staining at different pHs in both control group and SC group.

AB pH 1 technique, which allowed the identification of GPs with O-sulfate esters, showed a slightly positive reaction at Brunner Glands of both diet groups. However SC group’s neutral mucosubstance in Brunner glands were

moderately stained by PAS, control groups’ were showed slightly positive reaction (Fig. 3 A,B). Also Brunner glands at both diet groups were strongly stained blue with AB pH 2.5 which allowed the identification of GPs with carboxyl groups. They were stained strongly positive at SC group on the other hand moderately stained at control group with PAS/AB pH 2.5; to demonstrate GPs with carboxyl groups and GPs with O-sulfate esters (Fig. 4 A,B). Both diet groups were stained moderate red by PAS/AB pH 1.

**DISCUSSION**

This study contains the histological and histochemical changes of duodenum after feeding rabbits with SC. In our study, we observed that total mucosa height was higher in the SC group compared with those in the control groups. This result was related with increasing villus height. However, the difference was not statistically significant. It is assumed that an increased villus height is paralleled by an increased digestive and absorptive function of the intestine due to increased absorptive surface area.\(^{[15]}\)

According to Buts et al.\(^{[16]}\) *Saccharomyces* have a positive effect on the villus height. Likewise, Baum et al.\(^{[17]}\) also found that villus length was greater in the small intestine of piglets fed yeast than controls. In addition, it was indicated that longer villi are correlated with activation of cell mitosis.\(^{[18]}\) Hence, our results confirm this hypothesis that these yeasts could stimulate the development of the intestinal villi by an increasing cell proliferation.

In the present study, a greater villus and shorter crypts were observed in SC fed rabbits. Santin et al.\(^{[19]}\) reported very similar results in that SC added at 0.2% of broiler diets that a reduction in crypt depth and an increase in villus height. Likewise, Bradley et al.\(^{[20]}\) reported that crypt depth in the ileal mucosa was reduced when the broiler diet was supplemented with SC. In this study the Brunner’s glands in the duodenum of the group feeding with SC was found to be higher than those in the control group but not...
in combination with standard antibiotics for identification of prebiotic fructooligosaccharide. The effect of heat stress and environmental toxins, and some dietary components lytic enzymes invasion of enteric bacteria, bacterial and tract protects the epithelial cells and mucosa from proteo-

different histochemical techniques in the duodenal glands of the Brunner's glands. In mammals, GPs layer of gastrointestinal depth may be increased by SC's inducing the enlargement statistically significant. This study showed that the gland may be increased by SCs inducing the enlargement of the Brunner's glands.

Also, we demonstrated the presence of GPs with different histochemical techniques in the duodenal glands of the groups. In mammals, GPs layer of gastrointestinal tract protects the epithelial cells and mucosa from proteolytic enzymes invasion of enteric bacteria, bacterial and environmental toxins, and some dietary components. This glycoprotein compounds also known as mucins which secreted by goblet cells. Various authors have suggested that goblet cells contain neutral or acidic mucin glycoproteins or the combination of both types of mucin. In classic carbohydrate histochemistry, positive PAS reaction indicates the presence of neutral carbohydrate, while positive Alcian Blue reactions at pH 1.0 and 2.5 indicate the presence of acidic sulphated and acidic carboxylated residues respectively. Mucin synthesis and secretion are influenced by the diet. However, in the present study, staining properties with PAS, Alcian blue (pH 1.0 and 2.5) and PAS/AB (pH 1.0 and 2.5) of goblet cells not showed marked differences between two groups. There was no effect of the SC on mucins, which secreted by goblet cells. This result may be due to the use of low dose of SC. In the present study, the Brunner's glands were stained strongly positive with PAS and PAS/AB pH 2.5 in the SC treatment group than those of the control group. But, they were stained slightly with AB pH 1 in both diet groups. Our results showed that neutral and acidic mucins were enhanced by feed supplemented with SC in the Brunner's glands. The results suggest that SC have to be protecting against enteric pathogens. Ozpinar et al. also reported, SC protects from invading pathogens by mucosal immunity.

In conclusion, the addition of SC to the diet of rabbits affected the morphology of the duodenum by increasing the total mucosa, villus height, and the gland depth with inducing enlargement of the Brunner's glands. However, the addition of SC also little affected the histochemical features of the duodenum by increasing the secretion of neutral and acidic mucins in the Brunner's glands. We think that the effects may be generally related to the dose of SC. It may be proposed that higher doses of yeast may be used for digestive health. In addition, further studies are necessary to obtain definitive evidence on the effects of yeast supplementation on digestive system.
