Dear Editor,

Many inhaled or aspirated vegetal foreign bodies can be encountered in veterinary practice [1-4]. The most common ones are grass inflorescences that these foreign bodies migrate from trachea to the pulmonary parenchyma [1]. Although radiology and the other advanced techniques present diagnose of the foreign bodies [1,3,4], bronchoscopy is the best of all for diagnoses and removal of the foreign bodies [1] instead of the invasive approach by thoracotomy plus bronchotomy reported [2]. This letter reports to olive pit as an inhaled novel foreign body and its removal from the left main bronchus by bronchoscopy.

A 2 month-old, Belgium Malinois breed male puppy was presented with complaint of the coughing and vomiting reflexes following an olive eating. Clinically inspiratory dyspnea, thoracoabdominal respiration, intermittent vomiting and hemoptysis were determined. When the puppy laid down the lateral recumbent, dyspneic respiration was increased. Thus, respiration movements were closely monitored. The other vital parameters of the puppy were normal, and laboratory analysis results of the blood sample taken from peripheral vein were also within normal reference rates. Aspiration pneumonia was suspected and thoracic radiographs were taken immediately. In lateral radiograph, an olive pit-shape foreign body back of the carina was clearly observed in the tracheal lumen (Fig. 1A). Dexamethasone 0.25 mg/kg iv (Dekort®, Deva, Istanbul), amoxicillin clavulanate 15 mg/kg, im (Amoklovin®, Deva, Istanbul) and n-acetylcysteine 10 mg/kg, iv (Assist®, Bilim ilac, Istanbul) were given parenterally to relieve the respiration and prevent the secondary pulmonary infection. After sedation with xylazine HCl (Alfazine®, Egevet, İzmir) (1 mg/kg, im), 1/1 combination of the ketamine HCl (Alfamine®, Egevet, Izmir) (10 mg/kg) plus diazepam (Diazem®, Deva, Istanbul) (0.5 mg/kg) was administered intravenously for general anesthesia and maintenance. Intubation was provided 6.5 no endotracheal tube and 5.2 mm diameter flexible bronchoscope (Karl Storz®, Germany) was inserted through the inside of the intubation tube. Intraluminal endoscopy revealed the olive pit in the left main bronchus (Fig. 2). The fluids in the luminal passage were aspirated and a cage-shaped foreign body forceps was inserted to the lumen. The olive pit was caught and then removed (Fig. 3). The lateral thoracic radiograph was taken as control (Fig. 1B). Antibiotherapy (amoxicillin clavulanate) and muco-lytic (n-acetylcysteine) applications were continued to prevent the pulmonary infections and bronchial fluids medically. The puppy was discharged from the clinics without any respiration complication at 3rd days after removal of the foreign body.
